FROM TEDIUM TO TRADECRAFT: *Deploying AI to the Front Lines of HUMINT Operations*

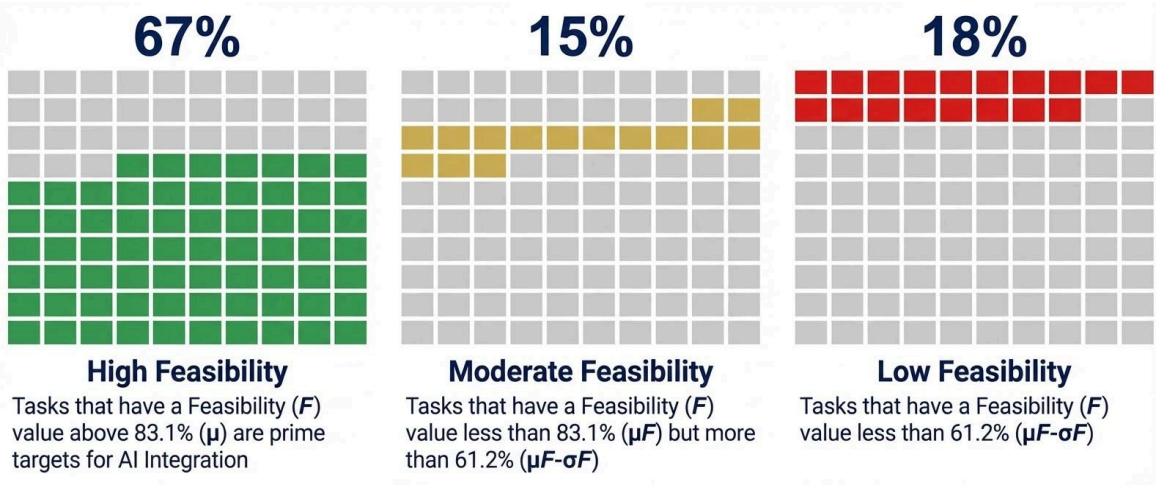
Researcher: CW2 Jonathan Capers, HUMINT Technician, U.S. Army

Institution: National Intelligence University | Master of Science in Strategic Intelligence

BOTTOM LINE UP FRONT (BLUF): The current push to integrate Artificial Intelligence (AI) into tactical HUMINT operations frequently treats all task sub-steps as equally automatable, inadvertently ignoring operational risk factors and data fidelity challenges. By cross-referencing military doctrine with Cognitive Load Theory, this research mathematically proves that automation must be targeted specifically at extraneous task friction. Shielding the operator's working memory from administrative noise preserves their cognitive capacity for the high-risk, unautomatable core of human intelligence collection.

KEY OPERATIONAL FINDINGS:

- **The Echelon Divide:** Algorithms are better suited to operational management than to tactical collection. Commissioned and Warrant Officer tasks are, on average, 6% to 9% more feasible for AI integration than junior Enlisted tasks.
- **The Analytical Heavy-Lift:** 288 of the 426 evaluated tasks score above the 83% Feasibility (*F*) benchmark. By aggressively targeting these high-feasibility tasks for integration, the DoW can safely offload the massive data-processing load, preserving the operator's cognitive capacity for the high-risk, human-to-human tactical collection that algorithms cannot execute.
- **The Operational Boundary:** Of the 426 analyzed sub-steps, 76 tasks constitute the inextricably human core of the 35M mission. These tasks exist at the intersection of high cognitive load and low AI capability, strictly prohibiting automation.



DATA COLLECTION STRATEGY: To quantify the feasibility of AI integration, this study decomposed the US Army Individual Critical Task List for 35M (Human Intelligence Collector), 351M (Human Intelligence Technician), and 35A-2F (Human Intelligence Officer) into 426 distinct, measurable sub-steps. These tasks were cross-referenced with the US Department of Labor's O*NET database (GWAs) to standardize the functional units. To eliminate subjective estimations of AI capability, the model utilized a Microsoft Research dataset of 200,000 real-world LLM interactions to generate empirical automation probabilities.

THE MATHEMATICAL FRAMEWORK: The research relies on calculating objective metrics against the baseline of human working memory capacity (Miller's Limit, established at $L = 7$):

- **Cognitive Load (L):** The total number of GWAs occurring within a performance step.
- **Extraneous Ratio (E):** The empirical percentage of a task capable of being automated, calculated as the mean of AI-capable GWAs within the task.
- **Germane Delta (ΔG):** The Extraneous Ratio (E) multiplied by the Cognitive Load (L).
- **Integration Value (IV):** The absolute magnitude of freed cognitive capacity (ΔG) multiplied by the Data Fidelity (D). Grounded in Expected Utility Theory, Data Fidelity applies a multiplicative decay (0.80) for noise, context, and subjectivity, establishing a baseline of D=0.512.
- **Risk Index (RI):** A 4x3 matrix plotting NIST SP 800-30 and ATP 5-19 consequence scales against Lipton's explainability taxonomy, transforming algorithmic opacity into an exact probability multiplier.

FEASIBILITY & INTEGRATION RETURN ON INVESTMENT: To evaluate operational expected utility, the final Feasibility (F) score utilizes a Pythagorean Expectation formula to weigh the squared Integration Value against the squared Risk Index:

$$F = \frac{IV^2}{IV^2 + RI^2}$$

- **Phase 1 (Immediate Offload):** 288 tasks ($F > \mu F$) demonstrating high value and low risk, optimal for prioritizing curated AI tool development and integration.
- **Phase 2 (Human-in-the-Loop):** 62 tasks ($\mu F > F > \mu F - \sigma$) requiring moderate oversight and phased integration.
- **Phase 3 (The Human Domain):** 76 tasks ($F < \mu F - \sigma$) lacking the necessary algorithmic capability for safe integration, or tasks bearing high operational risk, strictly reserved for human operators.
